Abstract

Background

The odd-scaled snake genus *Achalinus*, which is widely distributed in northern Vietnam, China and Japan, is a poorly-known group of snakes. Numerous species within this genus have been described based on few specimens or only a single type specimen. *Achalinus hunanensis* Ma, Shi, Xiang, Shu & Jiang, 2023 was described based on only

two male specimens from Huaihua City and Changsha City, Hunan Province, China. To date, this species has only been recorded in Hunan Province and the information on females is not available. During our herpetological surveys in 2024, two *Achalinus* specimens were collected from Guizhou Province, China. We compared morphology and mitochondrial DNA sequence data of these two specimens with all the species of the genus *Achalinus*. Both datasets strongly supported classification of the adult female specimen from Dushan County to *A. hunanensis* and the adult male specimen from Xifeng County to *A. yunkaiensis*.

New information

In this study, we describe the first female specimen of *A. hunanensis* in detail and provide revised diagnoses of this species based on newly-collected and examined specimens and update the distribution of *A. hunanensis* and *A. yunkaiensis*.

Keywords

Achalinus, China, morphology, phylogeny, Guizhou

Introduction

The genus *Achalinus* Peters, 1869 is the most speciose genus in the snake family Xenodermidae Gray, 1849, with 28 recognised species distributed from northern Vietnam, China to Japan (Ma et al. 2023c, Yang et al. 2023, Uetz et al. 2024). Most species of *Achalinus* are adapted to a semi-fossorial life, typically having small body sizes and inconspicuous colouration, which makes them difficult to detect in the wild. In recent years, with the advancement of field surveys and widespread DNA-barcoding efforts, the underestimated biodiversity of *Achalinus* has been gradually revealed. Since 2019, more than 20 new species of the genus *Achalinus* have been described (Wang et al. 2019, Ziegler et al. 2019, Li et al. 2020, Luu et al. 2020, Miller et al. 2020, Hou et al. 2021, Huang et al. 2021, Li et al. 2021, Ha et al. 2022, Yang et al. 2022, Ma et al. 2023b, Ma et al. 2023c, Zhang et al. 2023, Li et al. 2024, Xu et al. 2024b).

The Hunan odd-scaled Snake, *Achalinus hunanensis* Ma, Shi, Xiang, Shu & Jiang, 2023, was described, based on two male specimens and is currently known only from Huaihua City and Changsha City, Hunan Province, China (Ma et al. 2023b). It can be distinguished from its congeners mainly by a combination of the following morphological characters: (1) all dorsal scales strongly keeled, 23 rows throughout the body; (2) tail relatively short, TaL/TL ratio 0.221–0.225 in males; (3) maxillary teeth 23; (4) length of suture between internasals significantly longer than that between prefrontals; (5) one loreal, subrectangular; (6) six supralabials, the 4th and 5th in contact with the eye; (7) the two anterior temporals in contact with the eye; (8) ventrals 163–165, subcaudals 69–72 in males, not paired (Ma et al. 2023b).

During our recent herpetological surveys, two *Achalinus* specimens were collected from Guizhou Province, China (Fig. 1). Molecular data revealed that the adult female specimen from Dushan County clustered with the type series of *A. hunanensis*, while the adult male specimen from Xifeng County clustered with *A. yunkaiensis*. Subsequent morphological examination supported these results. In addition, when we examined the *Achalinus* specimens deposited in the collections of Chengdu Institute of Biology (CIB), Chinese Academy of Sciences, we found an adult male specimen from Anhua County, Hunan Province which was originally identified as *Achalinus ater*, but which we re-identified as *A. hunanensis*. Herein, we provide the first detailed description of the female of *A. hunanensis* and report the two new records of *A. hunanensis* and *A. yunkaiensis* from Guizhou Province.

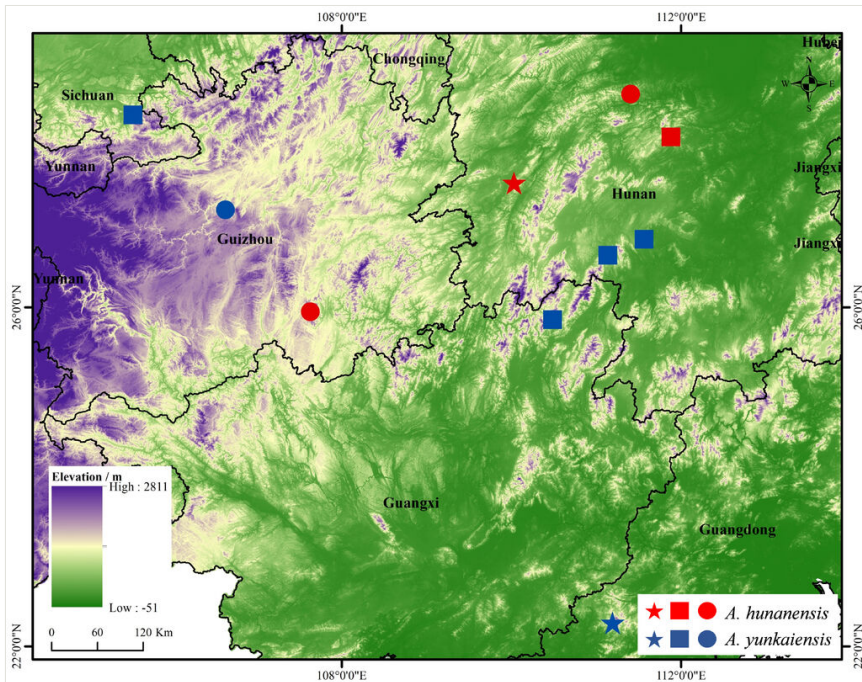

Figure 1. [doi](#)

Distribution of *Achalinus hunanensis* (red) and *A. yunkaiensis* (blue). The stars shows the type locality; the circles show the sampling point in this study; and the squares show the other known localities.

Materials and methods

Sampling

Two specimens of the genus *Achalinus* were collected in Guizhou Province, China: QHU 2024027 (field number LFR2024065), an adult male, was collected in Guiyang City and

QHU 2024030 (field number LFR2024120), an adult female, was collected in Qiannan Buyi and Miao Autonomous Prefecture. The specimens were humanely euthanised using a lethal injection of 0.7% tricaine methanesulphonate (MS222) solution. Fresh liver tissue was extracted and immediately preserved in 95% ethanol. The specimens were fixed in 10% formaldehyde for one day, then transferred to 75% ethanol for permanent preservation and deposited in Qinghai University Museum (QHU). All sampling procedures involving live snakes were in accordance with the Wild Animal Protection Law of China and approved by the Institutional Ethics Committee of Qinghai University (protocol code SL 2023028). Additionally, we examined a specimen deposited in the collections of the Chengdu Institute of Biology (CIB), Chinese Academy of Sciences: CIB 20160503, an adult male, was collected in Yiyang City, Hunan Province, China. The sex of all specimens was determined by gonadal dissection.

Molecular phylogeny

Genomic DNA was extracted from preserved liver tissues using QIAamp DNA Mini Kit (QIAGEN, Changsheng Biotechnology Co. Ltd). A fragment of the mitochondrial cytochrome c oxidase subunit 1 (*CO1*) was amplified by polymerase chain reaction (PCR) using primer pairs Chmf4 and Chmr4 (Che et al. 2012). The double-stranded PCR products were sequenced by Shanghai Map Biotech Co. Ltd.

CO1 sequences (621 bp) were assembled using SeqMan in the DNASTAR software package (Burland 2000) and compared using MEGA X software (Kumar et al. 2018). The Maximum Likelihood (ML) analysis was used with IQ-TREE 1.6.12 (Nguyen et al. 2015) to construct the phylogenetic tree. Ultrafast Bootstrap Approximation (UFB) branch support was assessed by using 5000 ultrafast bootstrap replicates and SH-like approximate likelihood ratio test (SH-aLRT) was conducted to the single branch tests by 1000 replicates. In addition, we calculated the uncorrected pairwise distances (*p*-distances) using the MEGA X software (Kumar et al. 2018).

For phylogenetic analysis, 32 sequences of 24 recognised species of the genus *Achalinus* were selected. Three outgroups: *Fimbrios klossi* Smith, 1921, *Parafimbrios lao* Teynié, David, Lottier, Le, Vidal & Nguyen, 2015 and *Stoliczka vanhnuailianai* Lalronunga, Lalmangaiha, Zosangliana, Lalmingliani, Gower, Das & Deepak, 2021 were selected following Xu et al. (2024). All sequences were obtained from National Center for Biotechnology Information (NCBI), except the newly-generated sequences (Table 1).

Morphological examination

Measurements and scale counts followed Zhao (2006) and Xu et al. (2024). The utilisation of abbreviations for morphological characteristics follows the conventions established by Darko et al. (2022). Three measurement characters were measured with Deli Stainless Ruler (No. 8462) to the nearest 1 mm: **SVL** (snout–vent length), **TAL** (tail length) and **TL** (total length). All other measurements were performed using Deli digital calipers (DL312200) to the nearest 0.1 mm: **HL** (head length): taken from the tip of snout to the posterior margin of mandible; **HW** (head width): measured at the widest part of the head in dorsal view; **LorH** (loreal height): measured from the highest part to the lowest part of the loreal in lateral view; **LorL** (loreal length): measured from the anteriormost to the posteriormost point of the loreal in lateral view; **LSBI** (length of the suture between internasals); **LSBP** (length of the suture between prefrontals); **ED** (eye diameter): taken from the anterior to the posterior edge of the eye. The scale characters and their abbreviations are as follows: **SL** (supralabials); **IL** (infralabials); **IL-1st Chin** (infralabials touching the first pair of chin shields); **Lor** (loreal); **PRO** (preoculars); **PO** (postoculars); **TEMP** (temporals); **aTEMP-Eye** (the number of anterior temporals touching the eye); **SPO** (supraoculars); **DSR** (dorsal scale rows): counted at one-head-length behind the head, at mid-body, at one-head-length before the cloacal plate; **VS** (ventrals), **CP** (cloacal plate) and **SC** (subcaudals).

Taxon treatments

Achalinus hunanensis Ma, Shi, Xiang, Shu & Jiang, 2023

Description of the female specimen (QHU 2024030)

Measurements and scalation. Measurements of the female *A. hunanensis* specimen are listed in Table 2. Body slender and cylindrical; head slightly wider than neck; eye small, ED 1.2 mm; rostrum small, triangular, slightly visible from above; length of the suture between the internasal substantially longer than that between prefrontal, LSBI 1.9 mm, LSBP 0.9 mm, LSBI/LSBP ratio 2.1; nasal divided into two sections by nasal cleft, nostril in the anterior part of the nasal; prefrontals paired; frontal pentagonal, pointed to the rear, slightly wider than high, much shorter than the parietals; loreal one, subrectangular, LorH 1.0 mm, LorL 1.6 mm, LorH/LorL ratio 0.63; supraocular one, pentagonal; TEMP 7/7, arranged in three rows (2+2+3 on both sides), the anterior two contact the eye; six supralabials, the 4th–5th contact the eye, the last one much elongated; two pairs of chin shields, the anterior pairs almost equal to the posterior pairs, followed by preventrals; one mental; 6/6 infralabials, the first one contacting with others after the mental and before the 1st chin-shields, 1st–3rd touching the first pair of chin-shields.

Table 2.

Morphological variation of *Achalinus hunanensis* obtained from specimens examined in this study and Ma et al. (2023b).

SC	53	69	69	72

Dorsal scales strongly keeled, lanceolate, 23 rows throughout the body, the outermost row strongly keeled and substantially enlarged. VS 169; anal entire; SC 53, not paired.

Colouration in life. In life, dorsum (head, body and tail) predominantly brownish-black, slightly tinged with iridescence. Head scales in dorsal view coloured like body. Eyes completely black, pupil vertically subelliptic. Supralabials mostly brownish-black. Mental, infralabials, chin shields and the 1st ventral brownish-black. Ventral ground colour light creamy-yellow, darker on the sides, the outer one-sixth of the

ventrals light brown. Ventral part of tail pale brown, gradually darkening towards the tip. The posterior margins of ventral scales are pale creamy-white (Fig. 2).

Figure 2. [doi](#)

Achalinus hunanensis in life, dorsal view (A) and ventral view (B). A1–B1: CIB 20160503, adult male; A2–B2: specimen QHU 2024030, adult female. A1–B1 photos by Ke-Ji Guo, A2–B2 photos by Yu-Hao Xu.

Colouration in preservation. After one month preservation, the colouration still resembles the specimen in life, except that the colouration of dorsum further deepens and the background colour of the venter becomes uniform pale brownish (Fig. 3).

Variation. The female specimen exhibits similar colouration to the male specimens, but differs in measurements and scalation characters as follows: the examined female has a relatively larger body size (TL 428 mm vs. 262–379 mm in males); a significantly shorter tail, TAL/TL ratio 0.17 (vs. 0.22–0.24 in males); and fewer subcaudals (53 vs. 69–72 in males). The main morphological characters of *A. hunanensis* are listed in Table 2.

Revision of diagnostic characters

(1) dorsal scales strongly keeled, 23 rows throughout the body, the outermost row strongly keeled and substantially enlarged; (2) tail relatively short, TAL/TL ratio 0.22–0.24 in males and 0.17 in females; (3) maxillary teeth 23; (4) length of suture between internasals substantially longer than that between prefrontals, LSBI/LSBP ratio 2.0–2.1; (5) one loreal, subrectangular; (6) six supralabials, the 4th and 5th in contact with the eye; (7) the two anterior temporals in contact with eye; (8) ventrals 163–168 in

males and about 169 in females; (9) subcaudals 69–72 in males and about 53 in females, not paired.

Figure 3. [doi](#)

Achalinus hunanensis (QHU 2024030), female, preserved specimen. Photos by Yu-Hao Xu. Scale bars: 10 mm.

Distribution and habits

Currently, *Achalinus hunanensis* is known from Hunan Province: Anhua County, Hecheng District, Ningxiang County; and Guizhou Province: Dushan County (Fig. 1). The species was found in leaf litter in well-preserved montane evergreen broadleaf forests (550–1300 m a.s.l.).

Description of the specimen from Guizhou Province (QHU 2024027)

Measurements and scalation. The measurements and scalation characters of *A. yunkaiensis* are listed in Table 3. Body slender and cylindrical; head slightly wider than neck; eye small, ED 0.9 mm; rostrum small, triangular, slightly visible from above; the suture between internasals subequal to the suture between prefrontals, LSBI 1.3 mm, LSBP 1.2 mm, LSBI/LSBP ratio 1.1; nasal divided into two sections by nasal cleft, nostril in the anterior part of the nasal; prefrontals paired; frontal one, pentagonal, pointed to the rear, slightly wider than high, much shorter than the parietals; one loreal, subrectangular, wider than high, exact measurements are impossible due to injury; supraocular one, pentagonal; TEMP 8/7, arranged in three rows (2+2+4 in left and 2+2+3 in right), the anterior two in contact with the eye; six supralabials, the 4th–5th contacting the eye, the last one much elongated; two pairs of chin shields, the anterior pair almost equal to the posterior pair, followed by preventrals; one mental; 6/5 infralabials, the first pair in contact with each other after the mental and before the 1st chin shields, 1st–4th touching the first pair of chin shields on left and 1st–3rd touching the first pair of chin shields on the right.

Dorsal scales strongly keeled, 23 rows throughout the body, the outermost row smooth and substantially enlarged. VS 146; anal entire; SC 59, not paired.

Colouration in life. In life, all scales tinged weakly iridescent. Dorsum brown and the five innermost dorsal scale rows a little darker, forming an inconspicuous longitudinal vertebral line from posterior margin of the parietals to tail tip. Head scales in dorsal view the same colour as the dorsum and dorsal darker than lateral. Eyes completely black, pupil vertically subelliptic. Supralabials mostly brownish. Mental, infralabials, chin shields brown. Ventral ground colour of body and tail generally pale greyish-white and darker laterally. The posterior margins of ventral scales are greyish-white (Fig. 4).

Colouration in preservation. In preservation, colouration darkens. Dorsum taupe, the longitudinal vertebral line almost disappearing. The colouration of venter is fading and becomes pale brownish-grey (Fig. 5).

Distribution and habits

Achalinus yunkaiensis is currently known from several locations in China, including Maoming City, Guangdong Province; Guilin City, Guangxi Zhuang Autonomous Region; Yongzhou and Shaoyang City, Hunan Province; Guiyang City, Guizhou Province; and Luzhou City, Sichuan Province, at elevations ranging from 425 to 1600 m a.s.l. (Fig. 1). The species usually prefers to hide under rocks, decaying wood or fallen leaves and the surrounding environment is untouched subtropical monsoon forests.

Discussion

Molecular phylogenetic analysis revealed that sequence [OR344062](#) (voucher number: YBU 22050) clustered with *A. spinalis* with high support (SH 100/UFB 100) and the uncorrected *p*-distance was only 2.8%. However, Zhang et al. (2023) reported that this sequence formed a clade with the *A. yunkaiensis* type series, with low intraspecific genetic divergence ranging from 3.1% to 3.3%. Meanwhile, according to the data provided by Zhang et al. (2023), the female specimen YBU 22050 from Luzhou City, Sichuan Province shows the following distinctive morphological characters compared to the known female specimens of *A. yunkaiensis*: (1) tail relatively long, TaL/TL ratio 0.24 (vs. 0.16–0.20); (2) VS 145, SC 65, VS+SC 210 (vs. VS 144–156, SC 51–55, VS+SC

195–205); (3) length of suture between internasals significantly shorter than that between prefrontals, LSBP 17.7 mm, LSBI 11.6 mm, LSBI/LSBP ratio 0.66 (vs. LSBI = LSBP). This discrepancy is notably perplexing. Therefore, comprehensive sampling of both morphological and genomic data is necessary to better understand the population or species structure within *A. yunkaiensis*.

Recent studies using a combination of morphological and molecular analyses have revealed significant genetic divergences within the genus *Achalinus*, suggesting that the diversity of this genus has been greatly underestimated and many species seem to have very limited distributions (Wang et al. 2019, Ziegler et al. 2019, Miller et al. 2020, Hou et al. 2021, Ha et al. 2022, Yang et al. 2023, Zhang et al. 2023, Ma et al. 2023b, Ma et al. 2023c, Xu et al. 2024a, Xu et al. 2024b). However, the elusive lifestyles of *Achalinus* species have made it difficult for researchers to accurately assess their populations and distributions, posing challenges for conservation efforts. Currently, while *A. hainanus* Huang, 1975 is listed as "Vulnerable" (VU) and *A. weneri* Van Denburgh, 1912 as "Near Threatened" (NT) by the IUCN Red List of Threatened Species, the conservation status of most *Achalinus* species remains largely unassessed (Kidera and Ota 2017, Lau and Zhou 2017). Given their restricted ranges and vulnerability to overexploitation, all these species might need to be reclassified into higher threat categories following careful evaluation.

Previously, *A. hunanensis* was known exclusively from its type locality Hunan Province, with the holotype collected at an altitude of 880 m and the paratype at 1200 m (Ma et al. 2023b). However, the discovery of the female specimen QHU 2024030 at an altitude of 1300 m in Dushan County, Guizhou Province and the male specimen CIB 20160503 at 550 m in Anhua County, Hunan Province, substantially extends the known geographical and elevational range of the species. Additionally, the identification of *A. yunkaiensis* in Guiyang City also represents the first record of this species in Guizhou Province. The findings of this study increase the number of recorded *Achalinus* species in Guizhou Province to five and illustrate that the diversity of the genus in Guizhou may still be highly underestimated and additional surveys are required to understand the true diversity of *Achalinus* in southwest China.

Acknowledgements

We are deeply grateful to Dr. Gernot Vogel and Dr. Jianping Jiang for their meticulous and accurate English language editing. We are also grateful to Keji Guo for his assistance with photography and to Tianxuan Gu and Shu Li for their help with fieldwork. This work was supported by the Project of the National Natural Science Foundation of China [32301325], Qinghai Science & Technology Department (2024-ZJ-965), Central guided Local Projects of Lhasa (LSKJ202441) and the Open Project of State Key Laboratory of Plateau Ecology and Agriculture, Qinghai University [2023-ZZ-08].

Author contributions

YHX, MCC, SM, TYZ measured the specimens, analysed the data, constructed the phylogenetic tree and prepared the manuscript; LFP provided the funding for the field survey; LFP and SCS conceived and designed the study and reviewed the manuscript before submission. All authors have read and agreed to the published version of the manuscript.
