# COI and ND1 as DNA barcodes to identify *Taenia hydatigena* (Cestoda: Taeniidae) from canine small intestine on Hainan Island in China

 Yajun Lu, Siqi Yang, Jingwen Liu, Xixi Lu, Qiuyu Zhao

*Not peer-reviewed, not copy-edited manuscript.*

## Disclaimer on biological nomenclature and use of preprints

The preprints are preliminary versions of works accessible electronically in advance of publication of the final version. They are not issued for purposes of botanical, mycological or zoological nomenclature and **are not effectively/validly published in the meaning of the Codes**. Therefore, nomenclatural novelties (new names) or other nomenclatural acts (designations of type, choices of priority between names, choices between orthographic variants, or choices of gender of names) **should NOT be posted in preprints**. The following provisions in the Codes of Nomenclature define their status:

### International Code of Nomenclature for algae, fungi, and plants (ICNafp)

**Article 30.2:** "An electronic publication is not effectively published if there is evidence within or associated with the publication that its content is merely preliminary and was, or is to be, replaced by content that the publisher considers final, in which case only the version with that final content is effectively published." In order to be validly published, a nomenclatural novelty must be effectively published (Art. 32.1(a)); in order to take effect, other nomenclatural acts must be effectively published (Art. 7.10, 11.5, 53.5, 61.3, and 62.3).

### International Code of Zoological Nomenclature (ICZN)

**Article: 21.8.3:** "Some works are accessible online in preliminary versions before the publication date of the final version. Such advance electronic access does not advance the date of publication of a work, as preliminary versions are not published (Article 9.9)".

15 **Funding**

16 This study was supported by grants from the Natural Science Foundation of Hainan  
17 Province (2019RC223).

18 **Ethics approval**

19 Not applicable.

20 **Consent to participate**

21 All participants provided written informed consent.

22 **Consent for publication**

23 All participants obtained written informed consent for publication.

24 **Availability of data and material**

25 The data used to support the findings of this study are included in the article. All data  
26 are fully available without restriction.

27 **Code availability**

28 Not applicable.

29 **Authors' contributions**

30 Siqi Yang performed the experiments and wrote the manuscript. Jingwen Liu, Xixi Lu,  
31 and Qiuyu Zhao performed the experiments. Yajun Lu designed the study, performed  
32 revisions to the draft report, and approved the final manuscript.

33 **Acknowledgements**

34 The authors gratefully thank the Science and Technology Department of Hainan  
35 Province for the financial support and Academician Workstation for material support.

36 **Abstract**

37 DNA barcoding based on universal gene markers is a fast, accurate, and innovative  
38 approach for the molecular discrimination of species. Some species are particularly  
39 difficult to discriminate using a traditional morphological identification method  
40 because of severely damaged morphological features. In this study, cytochrome c  
41 oxidase subunit I (COI) and NADH dehydrogenase subunit 1 (ND1) were used as  
42 barcoding markers to distinguish *Taenia hydatigena* in dogs on the tropical island of  
43 Hainan. Therefore, geographic differentiation based on the COI and ND1 sequences  
44 amongst the specimens and other geographic isolates in GenBank was determined by  
45 calculating the genetic distances according to the Kimura 2-parameter (K2P) model  
46 and constructing a phylogenetic tree using the neighbour-joining (NJ) method.  
47 Barcoding gap, base composition, and base saturation were tested to assess the  
48 effectiveness of the barcoding marker COI and ND1 genes for specimen identification.  
49 In addition, we analysed the barcoding gap and saturation and performed molecular  
50 evolutionary analysis of the intraspecies and interspecies diversity of *Taenia*.

51 **Keywords**

52 Cytochrome c oxidase subunit I; DNA barcodes; NADH dehydrogenase subunit 1;  
53 *Taenia hydatigena*

## 54 **Introduction**

55 With the development of molecular biology, it is increasingly common to identify  
56 species by combining molecular biology with genetic evolution analysis (Young et al.  
57 2019). Molecular identification based on specific DNA sequence analyses has become  
58 a common technological tool used to identify new species and can make more  
59 accurate assessments within and between species biodiversity than other methods as  
60 well as serve as an effective supplement to traditional morphological identification  
61 (Valentini et al. 2009). DNA barcodes have been widely used in biological molecular  
62 identification and have great significance for uncovering biological diversity. DNA  
63 barcodes can be used to establish a large-scale classification system for biodiversity  
64 analysis through several species-specific DNA barcodes (Coissac et al. 2016). DNA  
65 barcodes also provide reliable species identification for all life stages and even for  
66 tissue debris (Hawlitschek et al. 2016).

67 The application of the barcode of the COI gene in the study of molecular biodiversity  
68 is increasing rapidly and continuously (Balech et al. 2018). There are approximately  
69 4.5 million COI gene barcodes in GenBank and BOLD (Barcode of Life Data  
70 Systems), including different individuals across 250,000 species. It has become a  
71 common phenomenon to identify different animals by using the barcode of the COI  
72 gene (Thaler et al. 2016). In the identification of some species, the COI gene is more  
73 suitable for identifying individuals (Laopichienpong et al. 2016). The COI gene may  
74 prove to be valuable in the identification of the early developmental stage of species  
75 (Jaakko et al. 2016).

76 *T. hydatigena* is a zoonotic tapeworm species. Cysticercus is a larva that can be  
77 widely parasitized in domestic animals with a high infection rate. Hainan is a high  
78 incidence area of parasitic diseases. Taenia is a highly diverse population, and using  
79 morphological methods alone may fail to identify some parasites accurately  
80 (Ulziijargal et al. 2019). In 2013, Minoru and colleagues constructed molecular  
81 phylogeny using mitochondrial genes to explain the genetic relationship among  
82 different Taenia (Minoru et al. 2013). Since two gene barcodes have been proven to  
83 have better resolution (Pennisi 2007), we use two genes, COI and ND1, as barcodes to  
84 reflect the diversity of *T. hydatigena* (Cestoda: Taeniidae) on Hainan Island, and we  
85 analyse the molecular evolution of Taenia using molecular genetics.

## 86 **Materials and methods**

### 87 **Sample collection and genomic DNA extraction**

88 An adult worm was obtained from the canine small intestine. The fresh worm was  
89 washed in physiological saline and stored in 70% ethanol until use. Approximately  
90 2-3 millimetres of worm was cut with a scalpel and washed three times with ddH<sub>2</sub>O.  
91 The small piece of worm tissue was digested in 100 µL Solution AB and 25 µL AD  
92 Buffer (Biotek, Beijing, China) for 10 min at room temperature followed by 5 min at  
93 95 °C and was subsequently added to 100 µL Solution AC (Biotek) to extract the  
94 genomic DNA.

### 95 **PCR amplification and sequencing**

96 The COI and ND1 genes were amplified from genomic DNA by polymerase chain

97 reaction (PCR). The primer sequences for COI were the forward primer  
98 5'-TTTTTTGGGCATCCTGAGGTTTAT-3' and reverse primer  
99 5'-TAAAGAAAGAACATAATGAAAATG-3'. The primer sequences for ND1 were  
100 the forward primer 5'-AGATTCGTAAGGGGCCTAATA-3' and reverse primer  
101 5'-ACCACTAACTAATTCACCTTTC-3'. Amplification reactions contained 10  $\mu$ L of  
102 2 $\times$ Power Taq PCR MasterMix (Biotek), 4  $\mu$ L of ddH<sub>2</sub>O, 1  $\mu$ L of each forward and  
103 reverse primer (10  $\mu$ M), and 4  $\mu$ L of template DNA (0.002  $\mu$ g/ $\mu$ L). The cycling  
104 conditions were as follows: 94 °C for 3 min, 35 cycles of 94 °C for 1 min, 55 °C for 1  
105 min and 72 °C for 1 min, followed by a final step of 72 °C for 5 min. PCR products  
106 were purified using a FastPure Gel DNA Extraction Mini Kit (Vazyme Biotech,  
107 Nanjing, China) and sequenced by the Sanger sequencing method (BGI, Beijing,  
108 China).

### 109 **Molecular evolution analysis**

110 The sequences generated were assembled and refined manually to obtain final  
111 high-quality sequences using ApE software v2.0.61  
112 (<http://jorgensen.biology.utah.edu/wayned/ape>). Multiple sequence alignment was  
113 conducted for the sequences of the samples for COI and ND1, the selected sequences  
114 of 29 geographic isolates for COI, and 21 geographic isolates for ND1 from the  
115 GenBank database using the Basic Local Alignment Search Tool (BLAST) of NCBI  
116 (National Center for Biotechnology Information)  
117 (<https://blast.ncbi.nlm.nih.gov/Blast.cgi>). The phylogenetic trees were constructed  
118 using the neighbour-joining (NJ) algorithm. The intraspecific and interspecific genetic

119 distances were calculated using the Kimura 2-parameter (K2P) model, and the  
120 nucleotide composition, nucleotide frequencies, nucleotide pair frequencies, and  
121 transition/transversion ratios were analysed using MEGA-X software.

### 122 **Haplotype diversity analysis**

123 Haplotype diversity (Hd) was evaluated using DNA Sequence Polymorphism (DNAsp)  
124 v6.0 software by calculating the number of segregating sites (S), the average number  
125 of nucleotide differences per site (pi), and the total number of mutations.

### 126 **Effectiveness assessments of the barcoding markers**

127 The barcoding gaps of the markers for COI and ND1 genes were detected using  
128 automatic barcode gap discovery (ABGD). The values of substitution saturation were  
129 calculated using Data Analysis in Molecular Biology and Evolution (DAMBE)  
130 v7.2.14 software.

## 131 **Results**

### 132 **Morphological characters**

133 The adult worm was opalescent-yellowish and measured 122.4 cm in length. The  
134 strobila had 250-300 proglottids. The immature proglottids were wider than longer,  
135 and the mature proglottids were longer than wide at 10-14 mm long and 4-5 mm wide.  
136 A mature proglottid had an ovary and 600-700 testes. The uterus, filled with eggs, had  
137 5-10 uterine branches with smaller branches in a gravid proglottid.

138 Each genital pore was unilateral and irregularly alternating. The eggs were oval in

139 shape and approximately 36-39 mm in size, containing an oncosphere (Figure 1).

#### 140 **Phylogenetic characteristics**

141 A 422-bp fragment of the COI gene was successfully amplified, and a 385-bp  
142 fragment was retained after manual editing. Additionally, a 502-bp fragment of the  
143 COI gene was successfully amplified, and a 471-bp fragment was retained after  
144 manual editing. The phylogenetic tree of the COI sequence (Figure 2) showed that *T.*  
145 *hydatigena* Hainan isolates had the closest relationship with *T. hydatigena* from Iran  
146 (Table 1), and the phylogenetic tree of the ND1 sequence (Figure 3) showed that *T.*  
147 *hydatigena* Hainan isolates had the closest relationship with *T. hydatigena* from  
148 Kenya (Table 2). The nucleotide sequence homology among the *Taenia hydatigera*  
149 was very similar, showing high homogeneity. For the ND1 gene, the genetic  
150 relationship between *Taenia hydatigera* and *Taenia saginata* was the furthest.

#### 151 **Genetic diversity analyses**

152 A total of 15 haplotypes were obtained from the sequence alignment of 29 isolates  
153 based on the COI gene: the haplotype diversity was 0.8276, the nucleotide diversity  $\pi$   
154 was 0.07769, and the number of segregating sites was 130. The average content of the  
155 A, T, C, and G bases from the COI gene sequences was 22.3%, 44.7%, 9.6%, and  
156 23.5%, respectively, and the GC content was 33.1%. The COI gene contained 81  
157 variable sites. The transitional pairs (si) were 10, and the transversional pairs (sv)  
158 were 13 with a si/sv ratio of 0.77.

159 A total of 15 haplotypes were obtained from the sequence alignment of 21 isolates

160 based on the ND1 gene: the haplotype diversity was 0.9381, the nucleotide diversity  
 161  $\pi$  was 0.12544, and the number of segregating sites was 260. The average content of  
 162 A, T, C, and G bases from ND1 gene sequences was 19.7%, 51.6%, 6.5%, and 22.3%,  
 163 respectively, and the GC content was 28.8%. The ND1 gene contained 94 variable  
 164 sites. The transitional pairs (si) were 10, and the transversional pairs (sv) were 11 with  
 165 a si/sv ratio of 0.91. The transversional pairs of the COI gene turned into a straight  
 166 upward trend with increasing genetic distance, and when the base conversion  
 167 proportion was 3%, the platform period appeared. For ND1, both transitional pairs  
 168 and transversional pairs had a platform period. The mutation of the ND1 gene reached  
 169 a saturation state (Figure 4).

#### 170 **Effectiveness of the barcoding markers**

171 The COI gene had obvious DNA barcoding gaps. The DNA barcoding gaps of the  
 172 COI gene were 0.03-0.12 and 0.20-0.30, and the DNA barcoding gap of the ND1 gene  
 173 was 0.45-1.25 (Figure 5). The COI and ND1 genes both showed DNA barcoding gaps  
 174 within and between populations, and they had a certain genetic interval; therefore,  
 175 they could be used to distinguish species.

176 We used MEGA-X to calculate the genetic distance within and between different  
 177 tapeworms in COI and ND1. For COI, the maximum genetic distance was between  
 178 *Taenia saginata* and *Taenia taeniaformis*. The genetic distance between *Taenia*  
 179 *saginata* and other worms was far. For ND1, the results showed that the genetic  
 180 distance between *Taenia hydatigera* and *Taenia saginata* was the largest, and they had

181 the furthest genetic relationship. The histogram of distance shows that the COI  
182 sequence set is divided into 8 distinct groups, and the ND1 sequence set is divided  
183 into 7 distinct groups.

## 184 **Discussion**

185 *T. hydatigera* is an endoparasite that causes human and animal infections. Adult  
186 worms inhabit the small intestine of canines, wolves, and other canids. The larvae  
187 disseminate to the livers, lungs, and various other organs of livestock and wildlife.  
188 Humans usually develop infections from ingesting food and water contaminated by  
189 parasite eggs in canine faeces. In 2003, Hebert et al. first proposed the term DNA  
190 barcoding (Hebert et al. 2003) as a technique to identify organisms. DNA barcoding is  
191 an efficient tool for distinct species (DeSalle et al. 2005; Frézal and Leblois 2008).  
192 Accumulating evidence shows that the COI gene can serve as the core of a global  
193 bioidentification system for animals. The COI gene can distinguish species at the  
194 DNA level. A DNA barcoding technique based on the molecular evolution of the COI  
195 gene is a reliable classification method. The COI gene is a general DNA barcoding  
196 marker; nevertheless, the molecular identification rate of sibling species or related  
197 species of ecogeographical groups is relatively low. In addition, DNA barcoding  
198 markers of multiple genes have better discriminability than a single gene as a DNA  
199 barcoding marker. An outstanding DNA barcoding marker requires that there is an  
200 obvious barcoding gap between intra- and interspecific distances. The average  
201 interspecific distances were more than 10-fold larger than the average intraspecific  
202 distances (Paul et al. 2004). Therefore, we used the COI and ND1 genes as DNA

203 barcoding markers to identify the species of the worm and analysed the phylogenetic  
204 relationships of the specimen and different geographic isolates in this study. The *T.*  
205 *hydatigena* Hainan isolate had the closest phylogenetic relationship with the *T.*  
206 *hydatigena* Chabahar isolate from Iran based on the COI gene. The *T. hydatigena*  
207 Hainan isolate had the closest phylogenetic relationship with the *T. saginata* Kenya  
208 isolate from Iran based on the ND1 gene. The phylogenetic tree and genetic distance  
209 showed that the genetic distance between *Taenia saginata* and other worms was far.  
210 Two different genes had the same result. Through the existence of a barcode gap, we  
211 could automatically classify species sequences. The existence of a barcode gap proved  
212 that species can be distinguished effectively (Puillandre et al. 2011). The COI gene  
213 and the ND1 gene both showed an obvious barcode gap. There were two barcode gaps  
214 in the COI gene. These results suggest that the identification effect of the COI gene is  
215 better in species and interspecies of *Taenia*.

216 After the analysis of bases, we found that the haplotype diversity, base polymorphism,  
217 and polymorphic isolate sites of the ND1 gene were all high. In addition, the mutation  
218 of the ND1 gene reached a saturation state. Mitochondrial genes often have mutation  
219 saturation and a rapid mutation rate, so in the process of species formation, a base site  
220 may have multiple mutations, which will lead to a reduction in genetic distance when  
221 comparing distant species (Blouin et al. 1998). Using the COI gene may be more  
222 accurate and suitable.

223 In conclusion, it is extremely important to use DNA barcodes for species  
224 identification, especially for species that are morphologically similar and difficult to

225 distinguish by morphological methods. At present, due to the wide application of  
226 DNA barcodes, many researchers have conducted research on DNA barcodes and  
227 have proposed methods with high precision and calculation efficiency to improve the  
228 classification and recognition of barcodes (Goldstein and DeSalle 2011). DNA  
229 barcode identification of species has a good perspective. The principle of DNA  
230 barcodes is to select highly conserved DNA coding regions or noncoding region  
231 fragments with subtle variation at the evolutionary level to identify species, but it is  
232 difficult to find such general standard sequence fragments. In the process of species  
233 identification, we should also consider the mutation saturation of bases and properly  
234 use the genetic information analysis of base transversion to improve accuracy. Our  
235 study is relevant for its identification of *T. hydatigena* in Hainan. Moreover, with the  
236 development of DNA barcode research, DNA barcode technology will significantly  
237 advance the biodiversity research field.

305 Figure 1. *T. hydatigena* tissues were made transparent in xylene.

306 The microscope magnification is  $\times 100$  in 1-A, C, and D.

307 The microscope magnification is  $\times 40$  in 1-B.

308

309 Figure 2. The COI NJ phylogenetic tree is shown for 29 different geographic isolates.

310 Different symbols indicate different species. There are five different kinds of *Taenia*

311 *spp.* The black circle denotes the *T. hydatigera* (Cestoda: Taeniidae) in Hainan

312 identified by the COI gene.

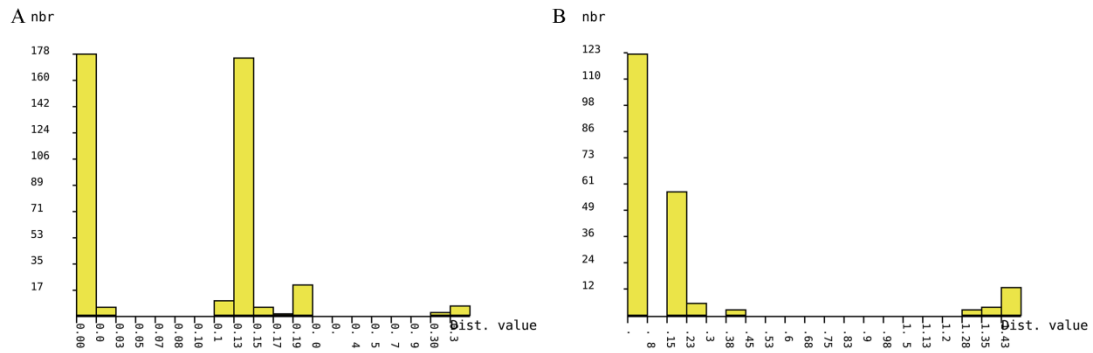

313

314 Figure 3. The ND1 NJ phylogenetic tree is shown for 21 different geographic isolates.

315 Different symbols indicate different species. There are three different kinds of *Taenia*

316 *spp.* The black circle denotes the *T. hydatigera* in Hainan identified by the ND1 gene.

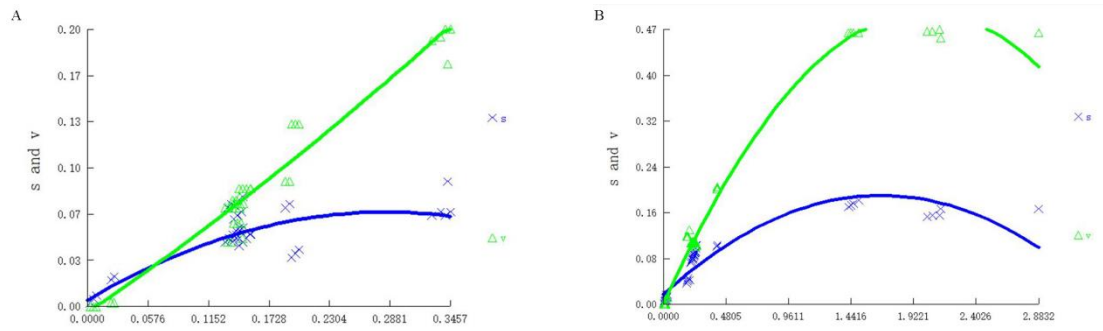

317

318 Figure 4. Results of barcoding gap analysis of 29 COI genes (A) and 21 ND1 genes

319 (B) generated by ABDG. The abscissa represents the distance value, and the ordinate

320 represents the numbers. Both genes showed an obvious barcoding gap.

321

322 Figure 5. Results of base saturation analysis of 29 COI genes (A) and 21 ND1 genes

323 (B). The abscissa indicates genetic distance, and the ordinate indicates base

324 substitution frequency.

325 Table 1. The COI gene of the 29 different geographic isolates
