Abstract

“*Octopus*” *rubescens* Berry, 1953 is an octopus of temperate waters of the western coast of North America. This paper presents the first record of “*O.*” *rubescens* from the tropical Mexican Pacific. Twelve octopuses were studied; 10 were collected in tide pools from five localities and two mature males were caught by fishermen in Oaxaca. We used morphometric characters and anatomical features of the digestive tract to identify the species. The five localities along the Mexican Pacific coast provide solid evidence that populations of this species have become established in tropical waters.

Keywords

Artisanal fishery, cryptic species, Gulf of Tehuantepec, Oaxaca, *Octopus*

Introduction

Nowadays, the generic status of most octopus species is unresolved generic and only nine species belong to *Octopus* Cuvier, 1797 *sensu stricto*. Other *Octopus*-like species that have been provisionally placed in the genus *Octopus* (denoted with quotation marks to indicate their unknown position) are awaiting generic revision (Norman et al. 2014). In the Mexican Pacific, the following species have been described: “*O.*” *bimaculoides* Pickford

& McConnaughey, 1949; “*O.*” *bimaculatus* Verrill 1883; “*O.*” *mimus* Gould, 1852; “*O.*” *hubbsorum* Berry, 1953; “*O.*” *chierchiae* Jatta, 1889; “*O.*” *alecto* Berry, 1953; “*O.*” *fitchi* Berry, 1953; “*O.*” *veligero* Berry, 1953; “*O.*” *penicillifer* Berry, 1954; “*O.*” *oculifer* Hoyle, 1904; and “*O.*” *rubescens*. However, there is little information on their geographic distribution.

“*Octopus*” *rubescens* Berry, 1953, Red Octopus, is

a small benthic octopus that reaches an average adult weight of 150–200 g, although some can reach as much as 400 g in weight (Hochberg 1997). Its life cycle spans from 12 to 18 months. It is a migratory species, moving offshore in the winter months. Its mating occurs in deep waters in the spring, followed by an onshore migration before spawning (Norman et al. 2014). The female has an average fecundity of 20,000 to 50,000 eggs (3–4 mm in length; mantle length (ML) of the pelagic paralarvae 1.7–2.0 mm) (Hochberg 1997).

This species is native to the temperate waters of the western coast of North America, inhabiting an extremely wide variety of habitats, including soft bottoms, rocky inshore and intertidal areas, and mud bottoms, from the intertidal zone to 300 m deep (Norman et al. 2014). It has a nocturnal and cryptic behavior, and its diet includes gastropods, bivalves, and decapod crustaceans (Hochberg and Fields 1980). “*Octopus*” *rubescens* is a prey for many marine species, including fishes, birds, and mammals (Norman et al. 2014). This species is commonly known as Red Octopus, and its distribution comprises the southern part of the Gulf of California, Mexico, to the Gulf of Alaska (Hochberg and Fields 1980). We present here the first confirmed occurrences of “*O.*” *rubescens* from Mexican tropical Pacific waters. These new records represent the southernmost limit of the geographic distribution of this species.

Methods

From December 2015 to February 2016 during a scientific research expedition in the eastern Pacific, 10 specimens of “*Octopus*” *rubescens* were encountered during several scientific dives in shallow waters (Fig. 1). Specimens were collected with clove oil (Seol et al. 2007) under two scientific collection permits, PPF/DGOPA-035/15 and PPF/DGOPA-116/17 issued by SAGARPA and CONAPESCA. Two additional specimens were caught on 18 February 2016 in El Faro, Puerto Angel, Oaxaca by fishermen, while diving at depths of 5 and 15 m and using a long hand hook. These specimens were fixed in 96% alcohol for 24 h, preserved in 70% alcohol, and deposited at the Cephalopod Collection of the Universidad del Mar (UMAR-CEPHA).

Octopuses were identified according to Roper and Voss (1983) and Hochberg (1998). Measurements were taken from each individual using digital calipers to the nearest 0.01 mm. All measurements and counts are as defined by Roper and Voss (1983). Measurements included: TL = total length; ML = dorsal mantle length; VML = ventral mantle length; MW = mantle width; HL = head length; HW = head width; AL = arm length; HAL = hectocotylized length; AW = arm width; WD = web depth; FL = funnel length; FFL = free funnel length; LL = ligula length; CL = calamus length. Sucker counts are totals per each intact arm. Gill counts do not include

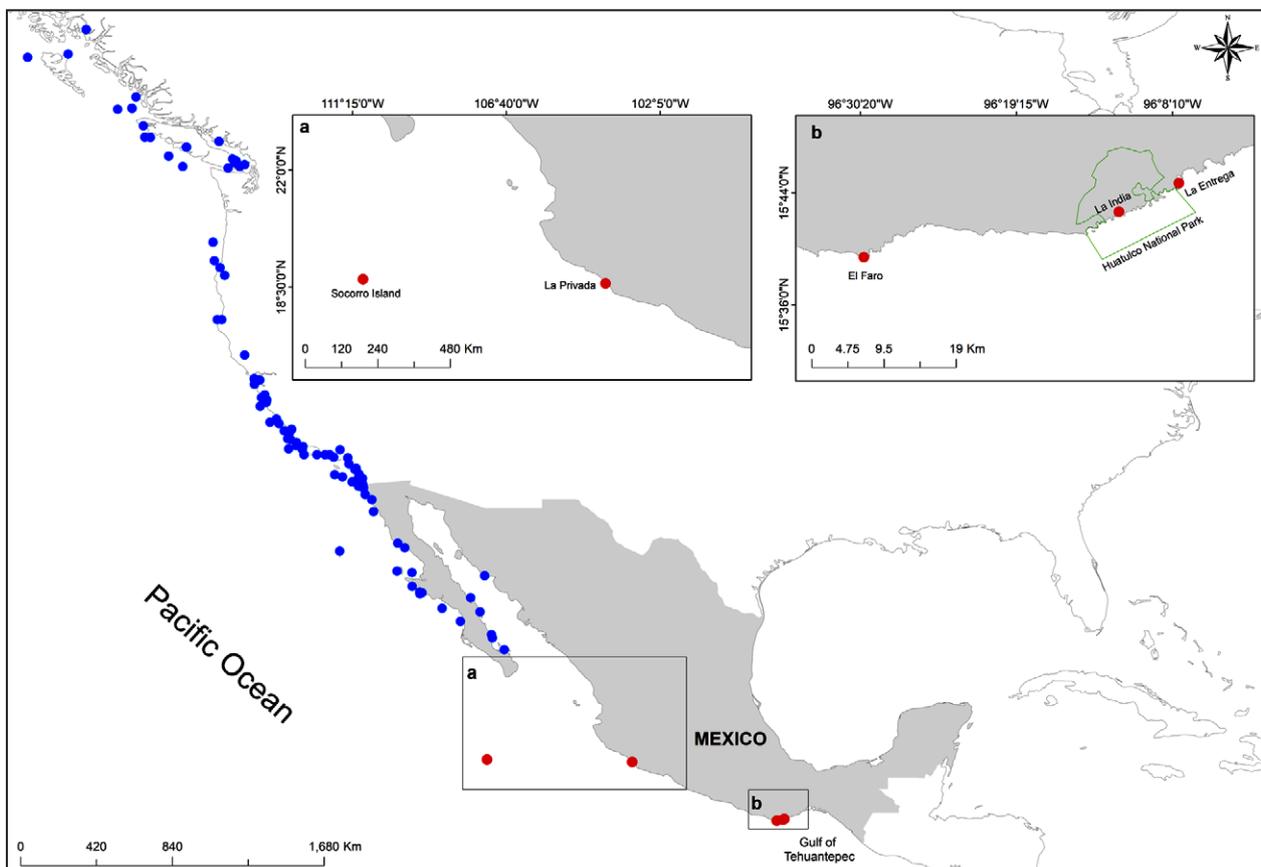

Figure 1. “*Octopus*” *rubescens* distribution on the Pacific coast. Blue points = previously known distribution, records obtained from GBIF. Red points = new records, this study.

terminal lamella. The measurements were provided as proportions of ML using the mantle proportion length index proposed by Roper and Voss (1983).

Total weight (W) was measured to the nearest 0.1 g. Sex was established through the observation of the gonads in all mature and immature specimens. The comparison of sexes was made only with adult individuals.

Results

Twelve records of “*Octopus*” *rubescens* from six localities in the Mexican tropical Pacific are presented here (Table 1). Juveniles and mature females were recorded in tide pools.

Materials examined. MÉXICO – Colima • Revillagigedo Archipelago National Park, Socorro Island, Braulia tidepool; 18°43'53"N, 110°57'20"W; 15 Dec. 2015; O. Valencia leg.; tide pool, scuba; UMAR-CEPHA 1153–1156 (4 ♀, 13.3, 19.1, 25.0, 31.61 mm ML) – Michoacán • playa La Privada; 18°36'15"N, 103°42'29"W; 12 m depth; 24 Feb. 2016; UMAR-CEPHA 1157–1160 (2 juveniles, 5.5, 9.57 mm ML, 2 ♂, 20.2, 21.2 mm ML) – Oaxaca • Bahía La Entrega; 15°44'35"N, 096°07'44"W; 5 m; 16 Jan. 2016; O. Valencia leg.; coral reef, scuba; UMAR-CEPHA 1161 (1 juvenile, 9.2 mm ML) • Bahía La India, Huatulco National Park; 15°40'47"N, 096°07'44"W; 5 m; 04 Dec. 2016; O. Valencia leg.; coral reef, scuba; UMAR-CEPHA 1162 (1 ♀, 16.8 mm LM) • El Faro, Puerto Ángel; 15°39'59"N, 096°29'35"W; 10 m; 18 Jan. 2016; artisanal fishermen leg.; rocky shores, free diving; UMAR-CEPHA 1163–1162 (2 ♂, 14.4, 19.5 mm ML).

Identification. A small octopus; ML usually <100 mm. Arms thin, 3–4× ML. Longest arms moderate to long, typically 3.0–4.5× ML, robust (AWI 15.9–20.4–26.5 %). Lateral arms longest 2>3>4>1 or 2>3>1>4 or 3>2>1>4. Hectocotyized arm with ~80–110 suckers; 1 or 2 conspicuously enlarged suckers present on all but ventral arms of mature males. Ligula well developed, elongate, conical, with distinct groove, and 10% of hectocotyized arm. Funnel length moderate, ~35% ML (FLI 16.1–52.9%), free portion funnel length 29.6% (FFLI 17.8–40.7%). Paleal aperture index 61.3% ML (API 39.4–74.2%). Mantle width index 81.3% (MWI 57.3–104.6%). Gills with 11 or 12 lamellae per demibranch.

Presence of specific characters: skin texture of patch and groove system with small or round patches; four primary papillae in a diamond pattern on the dorsal mantle; one large papilla on the mid-posterior dorsal mantle and one over each eye (Fig. 2A, B). Webs of moderate depth, web formula ABECD or ABEDC or AEBDC (Table 1).

The internal anatomy has not been completely described. We include for the first time a description of the digestive tract. A marked separation was observed between the two indistinct posterior salivary glands. Anterior salivary glands short, 33% of ML; posterior salivary glands 65.7% of ML. Digestive gland ovoid, with a weak iridescent sheen. Ink sac well developed,

Table 1. “*Octopus*” *rubescens*. Measurements and counts of preserved organisms. TL = total length; DML = dorsal mantle length; VML = ventral mantle length; MWI = mantle width index; HLI = head length index; HWI = head width index; EDI = eye diameter index; HALI = hectocotyized length; FLI = funnel length index; FFLI = free funnel length index; API = paleal aperture index; WDI = web depth index; AF = arm formula; GL = gill counts, do not include terminal lamella. Juv, juvenile; Mich = Michoacán; Rev = Revillagigedo Archipelago.

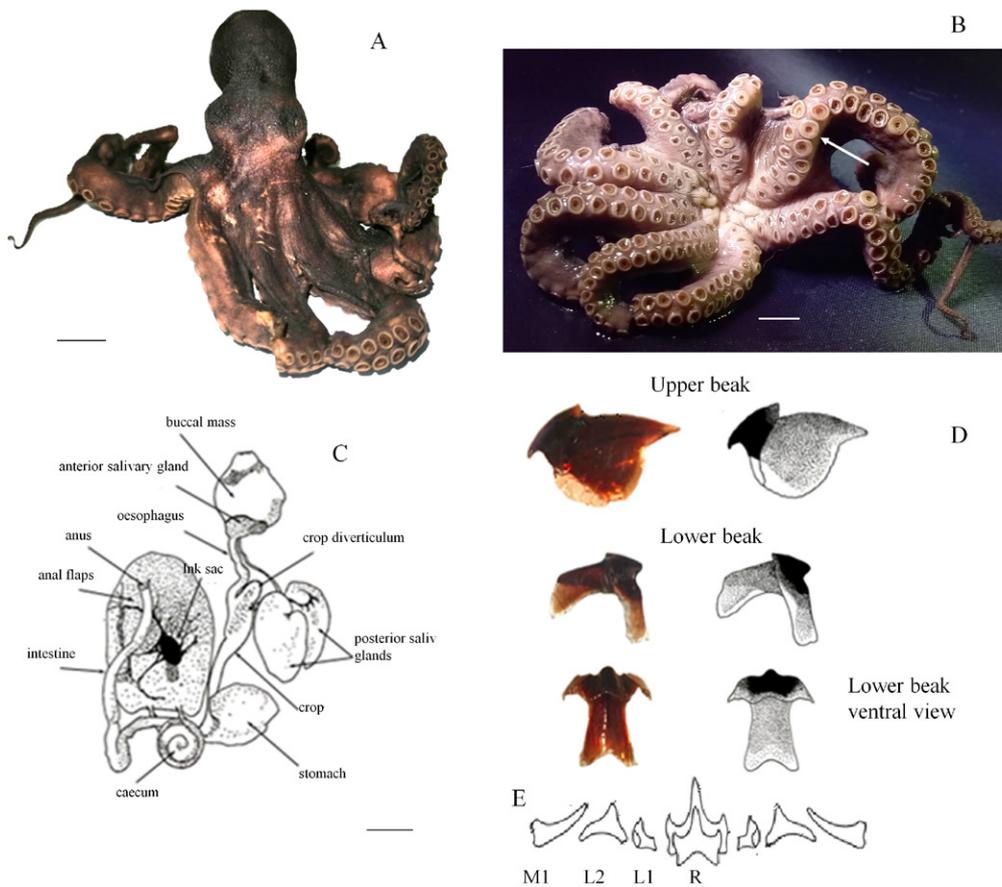

Figure 2. *Octopus rubescens*. **A.** Male (DLM = 21.2 mm), dorsal view. **B.** Oral view, scale 10 mm. **C.** Digestive tract. **D.** Beak, lateral view. **E.** Radula: R, radular tooth; L1 and L2, lateral teeth; M1, first marginal tooth. Arrow, arm 3 with enlarged suckers. Scale bars: A, B = 50 mm; C = 20 mm.

partly embedded in ventral surface of digestive gland. Anal flaps present and discrete. Esophagus straight; intestine muscular; caecum with 1.5 coils, distinctly striated (Fig. 2C).

Beaks: upper beak with a short, hooked rostrum; lower beak with narrow hood and lateral walls flared (Fig. 2D–F). Radula with seven teeth and two marginal plates per row; rachidian tooth with two moderate cusps, one each side (Fig. 2G).

Octopus rubescens (Fig. 3) has very distinctive characters that separate it from its congeneric species distributed along the Pacific coast of Latin America: *O. bimaculatus*, *O. hubbsorum*, *O. mimus*, and *O. oculifer*. *Octopus rubescens* can be distinguished from other octopuses present in the study area by its size and other morphological characteristics (Table 2), in addition to the following: a patch and groove skin texture with small, round patches; four primary papillae in a diamond pattern on the dorsal mantle; and one large papilla on the mid-posterior dorsal mantle and one over each eye. It is considerably smaller than congeneric species in the region: the ML of *O. rubescens* is 100 mm, vs. 220 mm in *O. hubbsorum* and 200 mm in *O. bimaculatus*. Gill lamellae number 11–13 in *O. rubescens*, vs. 9–11 in *O. hubbsorum* and 8–10 in *O. bimaculatus*. Ocelli are lacking in *O. rubescens*.

been placed in the genus *Octopus* (Norman et al. 2014). However, this species taxonomically fits in the genus *Octopus sensu stricto* (Norman et al. 2014) on account of the following: skin papillate; arms 3–5× ML; males with one or more enlarged suckers on all or some arms; formula typically 2>3>4>1 or 3>2>4>1; suckers large; skin with distinct patch; eyes not protruding; spermatheca present; copulatory organ with distinct ligula and calamus.

Our material fits well with the original description of the species by Berry 1953 and provided by Hochberg (1997). All measurements, counts and the patch and groove system of skin texture in our specimens match the descriptions of this species and are similar to those reported in records from the Gulf of California by Hochberg (1997). It is important include both morphological characteristics and quantitative attributes of octopuses.

Here, we record “*O.*” *rubescens* for the first time in Mexican tropical Pacific waters. Juveniles and mature females were recorded in tide pools. Huatulco, Oaxaca is now the southernmost limit of the geographic distribution

of this species. The two mature males captured by fishermen suggest that this species inhabits the central coast of Oaxaca and that “*O.*” *rubescens* can be part of artisanal catches of octopus. In this area, octopus fishing is artisanal and is carried out in shallow waters. “*Octopus*” *hubbsorum* is the most common octopus (Alejo-Plata et al. 2009), and “*O.*” *bimaculatus* has occasionally been observed in the captures (Alejo-Plata et al. 2014).

Thus, our new records are important documentation showing changes in the geographic ranges of organisms in the tropical Mexican Pacific. The geographic distribution of “*O.*” *rubescens* is extended from southern part of the Gulf of California to Puerto Ángel, Oaxaca, Mexico, approximately 2118 km southward. The five localities from the Pacific coast of Mexico are evidence that this species has established a population in tropical waters. However, more data is required to fully understand its ecology and distribution of “*O.*” *rubescens* in the Mexican tropical Pacific. Our study reflects the limited knowledge of octopuses in the region and suggests the need for increased sampling effort.

Acknowledgements

We express our gratitude to the numerous people involved in the fieldwork. We are grateful to the artisanal fishermen from Puerto Ángel, Oaxaca. MCAP thanks the Nacional de Investigadores (SNI-CONACyT). We also thank Helena Matthews-Cascon, Jaime Gomes, Sérgio de Almeida and Robert Forsyth for constructive comments on the manuscript. We declare that there is no conflict of interest.
