Abstract

The Tropical Screech-Owl (*Megascops choliba*) is a nocturnal raptor with a wide distribution across the Neotropics, which uses cavity trees as nesting and roosting sites. Our objectives were to address cavity use by the Tropical Screech-Owl in the piedmont forest of Argentina and to evaluate if logging affects the availability of suitable cavities for nesting and roosting and the frequency of response of the species to playback. The Tropical Screech-Owl used trees with DBH values > 46 cm of three tree species (69% *Calycophyllum multiflorum*, 15% *Phyllostylon rhamnoides*, and 8% *Cedrela angustifolia*), besides standing dead trees (8%). The density of suitable cavities was significantly lower in logged forests than in the control site. The frequency of response of the species to playback was significantly lower at one logged site. Our results can contribute to delineate sustainable forest management to ensure the conservation of this owl in logged forest.

Cavity-nesting birds, Forest management, Neotropical Owls, Yungas, Argentina

Introduction

Many bird species depend on the presence of cavities for nesting, sheltering or roosting (Martin *et al.* 2004; Collias & Collias, 2014). Thus, the abundance of these birds might be affected if the numbers of available cavities decrease (LaManna and Martin, 2017; Van der Hoek *et al.* 2017). Unsustainable logging can decrease the abundance of available cavities (Politi *et al.* 2012), therefore, it is important to assess the impact of this economic activity on biodiversity, especially in tropical and subtropical forests of the Neotropics, where the area under logging has increased (Hansen *et al.* 2013; Van der Hoek *et al.* 2017).

Nocturnal forest raptors are particularly sensitive to habitat change due to their specific nesting requirements and their large home ranges (Jullien and Thiollay, 1996; Rivera-Rivera *et al.* 2012). Moreover, nocturnal raptors play a key role in the ecosystem as top predators in trophic chains (Bildstein, 2001; Sergio *et al.* 2008). The Tropical Screech-Owl (*Megascops choliba*; Strigidae) is a nocturnal raptor which uses cavities as nesting sites and has a large distribution range from Costa Rica to central Argentina (Holt *et al.* 1999; Trejo *et al.* 2012). However, little is known about Tropical Screech-Owl habitat requirements (Dias and Lima, 2015). In Argentina, only anecdotal information exists on Tropical Screech-Owl cavity tree use and other nesting characteristics (de la Peña, 2005; Ruggera *et al.* 2016). Although the species is not categorized as threatened, forest degradation and transformation can negatively affect owl populations in Argentina (Trejo *et al.* 2012). Our objectives were to evaluate use and availability of tree cavity and frequency of responses of the Tropical Screech-Owl to playback in logged Piedmont forest of northwestern Argentina. We predict that logged forests will result in a lower availability of suitable cavities for Tropical Screech-Owl, and lower species' frequency of responses to playback.

Fieldwork was conducted in the Piedmont forests of Jujuy and Salta provinces in Argentina (Figure 1). This subtropical forest is found between 400 and 900 meters a.s.l. and is characterized by a highly seasonal climate, with annual rainfall values between 800 and 1000 mm concentrated during the summer between January and March (Arias and Bianchi, 1996). We selected four sites: one control located in Calilegua Nacional Park which has not been under logging for more than 40 years (Site 1: 23°38.181'S, 64°35.674'W), and three others that are currently under conventional logging (Site 2: 22°27.255'S, 63°58.553'W; Site 3: 22°05.373'S, 63°44.810'W; Site 4: 24°11.435'S, 64°34.449'W) (Figure 1). The sites are dominated by typical tree species of the Piedmont forest; such as *Calycophyllum multiflorum*, *Phyllostylon rhamnoides*, *Anadenanthera colubrina*, *Myroxylon peruiferum*, and *Astronium urundeuva* (Brown and Malizia, 2004).

At each site, we delimited an area of 100 ha where we conducted intensive searches for cavities used by the Tropical Screech-Owl during three consecutive breeding seasons from August to February (2014 to 2017). Searches were conducted along 4 to 6 transects per site of 1 to 1.5 km length and of 20 to 50 m wide. Encountered cavities were inspected with a mini-camera system attached to a 15 m

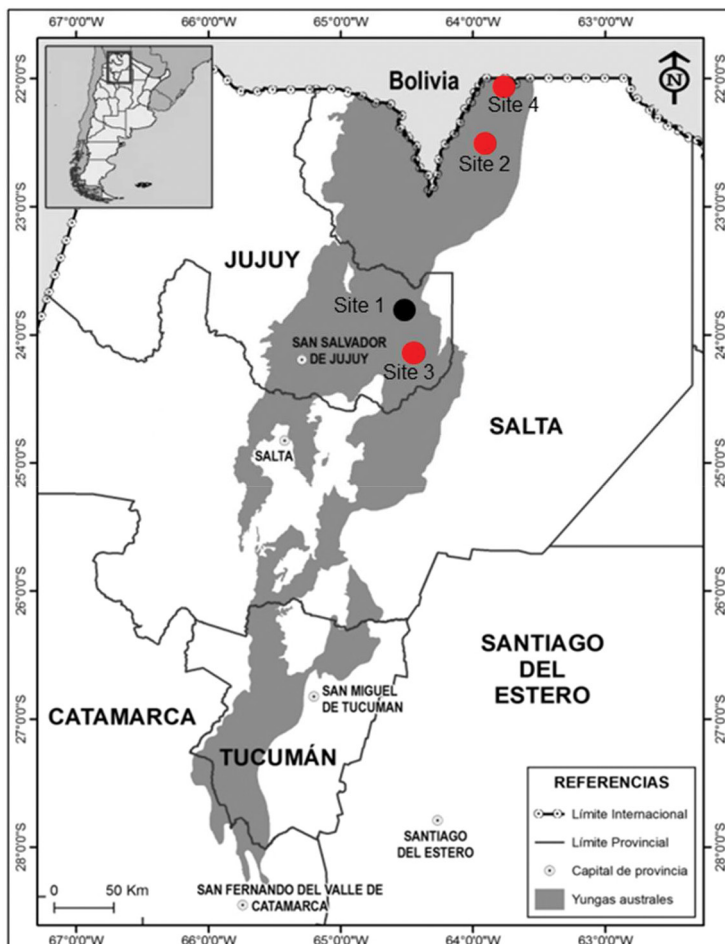

Figure 1. Location of the different study sites in the Piedmont forest of northwestern Argentina. Control site (1) and sites under logging (2, 3 and 4).

extendable pole (Richardson *et al.* 1999) to determine if they were used. In order to define suitable cavities for the Tropical Screech-Owl for each used cavity encountered we determined tree species and cavity origin (excavated by Woodpecker or decayed) and we measured tree diameter at breast height (DBH), cavity entrance height above the ground, horizontal and vertical entrance diameter (to determine cavity entrance area by using the formula of an ellipse), and internal cavity depth (Politi *et al.* 2010; Ruggera *et al.* 2016).

To determine the availability of suitable cavities for the Tropical Screech-Owl, we randomly selected 50 x 50 m plots (10 plots in sites 1 and 3 and 20 plots in sites 2 and 4) from a 100 ha grid (Politi *et al.* 2010). Suitable cavities were defined according to the characteristics used by the species, based on the range values of each characteristic defined in the result section.

At each site and within the 100 ha grid, we conducted 15 point counts to record the Tropical Screech-Owl from October 2016 to January 2017 in coincidence with the reproductive period of the species. Point counts were separated by at least 150 m, because of a minimum of 100 m is considered enough to avoid overestimation of individuals or the re-count of individuals (Borges *et al.* 2004). Point counts at each site were carried out during two or three consecutive days between 8h and 11h p.m., in coincidence with the highest peak of activity of nocturnal raptors. At each point count, we broadcasted a recording of the owl vocalizations (extracted from Xeno-canto Foundation 2008) for 10 minutes to elicit a vocal or visual response (Fuller and Mosher, 1987). We recorded frequency of responses of the Tropical Screech-Owl within a 50 m radius during the 10 minutes. Point counts were not conducted in adverse weather conditions (Hardy and Morrison, 2000; Rivera-Rivera *et al.* 2012). The number of responses of the Tropical Screech-Owl at each point count was used to calculate the frequency of responses at each site.

We compared the frequency of responses of Tropical Screech-Owl, the density of used cavities, cavity and tree characteristics (tree DBH, cavity height, cavity entrance size) of used cavities, and the density of used cavity trees species between sites with a Kruskal-Wallis test (H) due to the non-normal distribution of the data. All comparisons were performed with the INFOSTAT software, using a significance level of 0.05 (Di Rienzo *et al.* 2002).

We found a total of 13 cavities used by the Tropical Screech-Owl in decayed cavities in the following tree species: *Calycophyllum multiflorum* (69%), *Phyllostylon rhamnoides* (15%), and *Cedrela angustifolia* (8%), as well as in standing dead trees (8%). Used cavities were found in trees with a DBH of 47.83 ± 2.42 cm (range= 46.12 – 49.54 cm), cavity entrance height of 5.20 ± 0.75 m (range= 4.67 – 5.73 m), and cavity entrance area of 283.39 ± 81.04 cm² (range= 226.08 – 340.69 cm²) with a cavity depth > 10 cm. The frequency of responses of the Tropical Screech-Owl was significantly higher in control site than in logged site 4 (H= 8.58; $p < 0.05$) (Figure 2). The control site showed a significantly higher density of suitable cavities, higher DBH values, and higher density of suitable cavities of *C. multiflorum* and *P. rhamnoides* than logged sites (Table 1).

In logged Piedmont forest the lower availability of cavities suitable for the Tropical Screech-Owl may explain the lower frequency of responses to playback of the species as shown for other nocturnal raptors (Carrete *et al.* 2009). *Calycophyllum multiflorum*, *Phyllostylon rhamnoides*, and *Cedrela angustifolia* are highly valuable timber species and, consequently, have a high removal rates in logged sites resulting in a decrease in the density of these tree species (Politi *et al.* 2010). In site 4 we did not find cavity trees available of *P. rhamnoides* or *C. angustifolia*. In addition, the density of *C. multiflorum* with cavities was lower and cavity trees always had lower DBH values (Table 1). The frequency of the owl's response to playback may not have differed between the logged sites 2 and 3, and the control because there still are available cavities in *P. rhamnoides*, *C. angustifolia*, and standing dead trees.

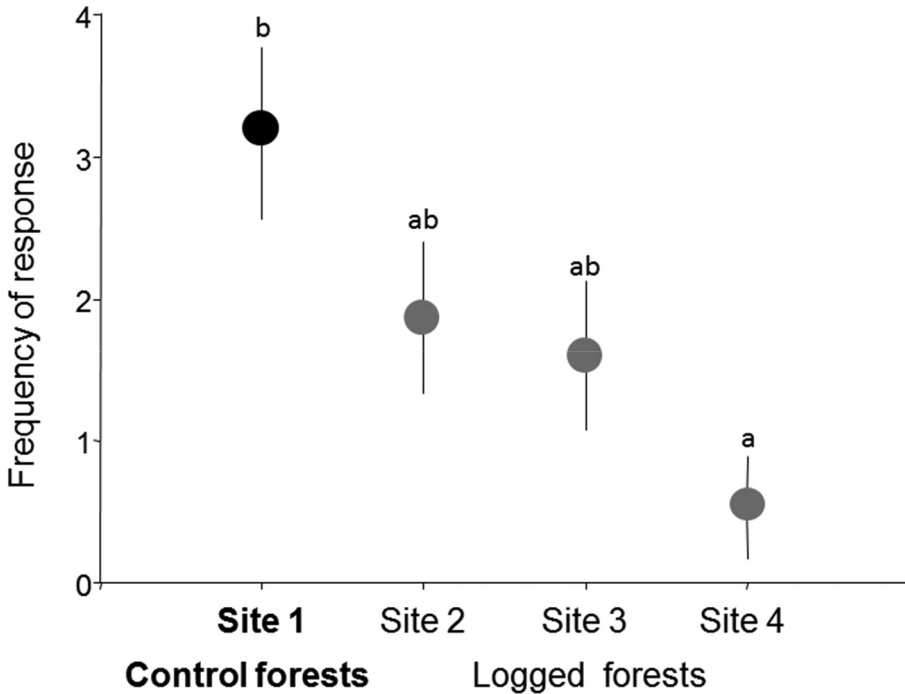

Figure 2. Frequency of response of the Tropical Screech-Owl in point count (mean \pm SE) using Raptor calls technique (playback) in three logged sites and one control site (not logged) in the Piedmont forest of northwestern Argentina. Different letters indicate significant differences between sites (Kruskal-Wallis tests; $p < 0.05$).

Logging operations in the Piedmont forest should retain trees of 46-50 cm DBH of those tree species which is the minimum size required by the Tropical Screech-Owl. The importance of large trees has already been stated for other cavity nesting bird species inhabiting the Piedmont forest (Albanesi *et al.* 2016; Ruggera *et al.* 2016). Although the Tropical Screech-Owl has been suggested to be a generalist species (de la Peña, 2005), it is worth noting its narrow tree size requirements (46-50 cm DBH), indicating that it may be a specialist species in the Piedmont forests regarding cavity tree requirements (Claudino *et al.* 2012; Dias and Lima, 2015).

While the results suggest the existence of a threshold in Piedmont forests regarding the density of suitable cavities (0.40 cavity/ha), below which the frequency of response to playback of this Owl decreases, it is necessary to point out that this particular species can be found in diverse environments (e.g., Open forest, urban parks or plantations; de la Peña, 2005; Enriquez, 2017). Therefore, thresholds cannot be generalized to other environments and further research is needed. The results of this study can be useful to delineate sustainable forest management guidelines to ensure the conservation of Tropical Screech-Owl and other biodiversity components in logged forests (Lindenmayer, 2000; Politi *et al.* 2009, 2010).

Table 1. Characteristics of trees and cavities suitable for the Tropical Screech-Owl and cavity density /ha in three logged sites and one control site in the Piedmont forests of northwestern Argentina. n= total plots; different superscript letters indicate significant differences between sites (Kruskal-Wallis tests; $p < 0.05$).

	Control site	Logged sites			H
	Site 1 n= 10	Site 2 n= 20	Site 3 n= 20	Site 4 n= 10

Resumo

Uso de cavidades arbóreas e frequência de resposta a playback pela corujinha-do-mato em região noroeste da Argentina

A corujinha-do-mato (*Megascops choliba*) é uma ave de rapina com hábitos noturnos e uma ampla distribuição neotropical que utiliza cavidades arbóreas para nidificação e alojamento. Nosso objetivo foi identificar o uso de cavidades pela corujinha-do-

mato na floresta piemonte na Argentina, e avaliar se a atividade exploratória afeta a disponibilidade de cavidades adequadas para nidificação e alojamento, bem como a frequência de resposta desta espécie. A corujinha-do-mato utiliza árvores com valores DAP > 46 cm para três espécies de árvores (69% *Calycophyllum multiflorum*, 15% *Phyllostylon rhamnoides*, e 8% *Cedrela angustifolia*), além de árvores mortas eretas (8%). A densidade de cavidades adequadas foi significativamente menor em florestas exploradas quando comparadas ao local de controle. A frequência de resposta foi significativamente menor em um sítio de exploração. Os resultados descritos aqui reforçam a importância do manejo florestal sustentável a fim de garantir a persistência dessa espécie de ave.
